Gunn rats, which have defects in bilirubin and 4-nitrophenol UDP-glucuronyltransferase (GT), were crossed with LA Wistar rats, which have a defect in androsterone GT. The F<sub>1</sub> hybrids showed normal GT activities towards androsterone, bilirubin and 4-nitrophenol, demonstrating that Gunn and LA (low activity) Wistar rats inherit a homozygous dominant trait for androsterone GT and bilirubin GT, respectively. The F<sub>2</sub> offsprings showed four different combinations of bilirubin and androsterone GT activities : defects in both GT activities, a single defect in bilirubin GT activity, a single defect in androsterone GT activity and two normal GT activities. They were segregated in the approximate ratio of 1 : 3 : 3 : 9, which is compatible with Mendel's Principle of Independent Assortment. These results provide evidence that androsterone GT and bilirubin GT are located on different chromosomes. In the F<sub>2</sub> generation, defective bilirubin and 4-nitrophenol GT activities were not segregated, indicating that these two mutant genes are closely linked on the same chromosome.
